

Which older odor observations change decisions?

Post hoc saved-data analysis | No new gameplay or trained model | Original continuation still fails: 9/10 passed

Benefit concentrates in a few cases

First shared-history divergence 17 cases

Later prefixes on the full-policy path 538 decisions, 23 cases

Left: all paired outcomes; top-three contribution ranking is post hoc. Positive values favor full history.

Middle: mixture-weighted cases at their first differing action. Recent-32 disagreement there is true by construction.

Right: mixture-weighted eligible prefixes after more than 32 observations, on the recorded full-history path.

All reconstructions retain the initial hit and permanent visitation ledger. Matching full history is not proof of better autonomous search.
